NOTIFICATION OF TRANSMITTAL OF
THE INTERNATIONAL PRELIMINARY
EXAMINATION REPORT
(PCT Rule 71.1)

Date of mailing
(day/month/year)

12.11.2001

Applicant's or agent's file reference
HL73059 001MJA

IMPORTANT NOTIFICATION

International application No.
PCT/GB00/03006

International filing date (day/month/year)
04/08/2000

Priority date (day/month/year)
06/08/1999

Applicant
FLYING NULL LIMITED et al.

1. The applicant is hereby notified that this International Preliminary Examining Authority transmits herewith the international preliminary examination report and its annexes, if any, established on the international application.
2. A copy of the report and its annexes, if any, is being transmitted to the International Bureau for communication to all the elected Offices.
3. Where required by any of the elected Offices, the International Bureau will prepare an English translation of the report (but not of any annexes) and will transmit such translation to those Offices.

4. REMINDER

The applicant must enter the national phase before each elected Office by performing certain acts (filing translations and paying national fees) within 30 months from the priority date (or later in some Offices) (Article 39(1)) (see also the reminder sent by the International Bureau with Form PCT/IB/301).

Where a translation of the international application must be furnished to an elected Office, that translation must contain a translation of any annexes to the international preliminary examination report. It is the applicant's responsibility to prepare and furnish such translation directly to each elected Office concerned.

For further details on the applicable time limits and requirements of the elected Offices, see Volume II of the PCT Applicant's Guide.

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT**

International application No. PCT/GB00/03006

I. Basis of the report

1. With regard to the **elements** of the international application (*Replacement sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this report as "originally filed" and are not annexed to this report since they do not contain amendments (Rules 70.16 and 70.17):*)
Description, pages:

1-19 as originally filed

Claims, No.:

1-23 as received on 12/09/2001 with letter of 10/09/2001

Drawings, sheets:

1/5-5/5 as originally filed

2. With regard to the **language**, all the elements marked above were available or furnished to this Authority in the language in which the international application was filed, unless otherwise indicated under this item.

These elements were available or furnished to this Authority in the following language: , which is:

- ☐ the language of a translation furnished for the purposes of the international search (under Rule 23.1(b)).
☐ the language of publication of the international application (under Rule 48.3(b)).
☐ the language of a translation furnished for the purposes of international preliminary examination (under Rule 55.2 and/or 55.3).

3. With regard to any **nucleotide and/or amino acid sequence** disclosed in the international application, the international preliminary examination was carried out on the basis of the sequence listing:

- ☐ contained in the international application in written form.
☐ filed together with the international application in computer readable form.
☐ furnished subsequently to this Authority in written form.
☐ furnished subsequently to this Authority in computer readable form.
☐ The statement that the subsequently furnished written sequence listing does not go beyond the disclosure in the international application as filed has been furnished.
☐ The statement that the information recorded in computer readable form is identical to the written sequence listing has been furnished.

4. The amendments have resulted in the cancellation of:

- ☐ the description, pages:
☐ the claims, Nos.:

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT**

International application No. PCT/GB00/03006

☐ the drawings, sheets:

5. ☐ This report has been established as if (some of) the amendments had not been made, since they have been considered to go beyond the disclosure as filed (Rule 70.2(c)):

(Any replacement sheet containing such amendments must be referred to under item 1 and annexed to this report.)

6. Additional observations, if necessary:

V. Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

1. Statement

VII. Certain defects in the international application

The following defects in the form or contents of the international application have been noted:
see separate sheet

Re.: Item V

The invention concerns a method of decoding an information carrier comprising a plurality of magnetic elements having the same width and wherein the relative positions of the elements represent the encoded information (cf. Figure 1a). Determination of the relative positions of the magnetic elements is based on an estimation of the dynamics of motion between an interrogation signal and the information carrier, such estimation using an estimate of the relative velocity determined element by element. Since all the elements have the same (given) width, no dedicated separate reference elements are needed for determining the velocity, thereby providing for space efficiency.

The method of claim 1 is not suggested by the available prior art. WO-A-96 31 790 concerns a tag of the type shown in Figure 9; although this document states at page 15, lines 28-31 that "it then becomes a simple matter to use the lengths and spacings of individual zones or pieces of magnetic material to represent particular code sequences", it is silent as to how the lengths and spaces are actually measured and there is no suggestion to decode the information using an estimate of the relative velocity between the interrogation signal and each of the magnetic elements. Although EP-A-0 790 572 suggests compensation of the effect of speed-variation of an optical bar code reader on detected relative widths of bar elements by measuring the scanning speed of successive characters each comprising a plurality of different-sized code elements and correcting the width values accordingly, it does not and cannot determine an estimate of the relative velocity between the interrogation signal and each of the elements since the width of each such element is a priori unknown, the element width being used as a means to encode the information carrier.

Dependent claims 2-23 concern preferred embodiments of the invention of claim 1 and thus likewise meet the requirements of novelty and inventive step.

Re.: Item VII

The relevant prior art of WO-A-96 31 790 and EP-A-0 790 572 is not acknowledged in the description, contrary to Rule 5.1(a)(ii) PCT.

The summary of the invention on description page 2 is not in conformity with the new

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT - SEPARATE SHEET**

International application No. PCT/GB00/03006

independent claim.

The description at page 3, lines 12-16 and page 6, lines 28-32 (variable element width) is in conflict with the method of claim 1 (elements having same width).

CLAIMS

1. A method of decoding an information carrier
comprising a plurality of magnetic elements supported
5 by, or incorporated in, a substrate, wherein the
elements are of substantially the same width and
wherein the relative positions of said magnetic
elements represents the information encoded by the
information carrier, the method comprising the steps
10 of:

i) applying an interrogation signal to the
information carrier so that each of the magnetic
elements are subjected, in turn, to the interrogation
signal;

15 ii) detecting the response signal of each of the
magnetic elements to said interrogation signal;

iii) processing each response signal detected in
ii) so as to determine an estimate of the relative
velocity between the interrogation signal and each of
20 the magnetic elements; and

iv) estimating the dynamics of motion between the
interrogation signal and the information carrier, by
consideration of the processed signals obtained in
iii), so as to determine the relative positions of the
25 magnetic elements.

2 A method according to claim 1, wherein said
magnetic elements comprise high permeability, low
coercivity material having an easy axis of
30 magnetisation.

3. A method according to claim 1 or 2, wherein said
interrogation signal comprises regions of high
saturating magnetic field contiguous with regions of
35 zero magnetic field.

4. A method according to any preceding claim, wherein the frequency of the detected response generated by said magnetic elements is a harmonic of the interrogation signal.

5

5. A method according to any preceding claim, wherein the frequency of the detected response generated by said magnetic elements is the second harmonic of the interrogation signal.

10

6. A method according to any claim 4 or 5, wherein a graphical representation of the response signal is obtained by plotting the amplitude of the detected signal against time, wherein the presence of a magnetic element is indicated by two half peaks of opposite polarity in the detected response signal.

15

7. A method according to claim 6, wherein the half peaks in the detected response signal are identified by the following steps:

20

i) obtaining a contiguous set of sample points from the detected response signal;

ii) sorting the samples points into an order of ascending magnitude;

25

iii) finding the median value from the sorted samples and subtracting this value from each of the sample points;

30

iv) testing the sample points in order to identify the peaks, wherein a positive polarity half peak is identified by the presence of lower magnitude signals either side of the signal point being tested, and a negative polarity half peak is identified by the presence of higher magnitude signal either side of the signal point being tested.

35

8. A method according to claim 7, wherein the relative

velocity between the interrogation signal and each of the magnetic elements is determined by:

i) determining the two positions either side of the peak at which the amplitude of the detected response signal is a predetermined fraction of the peak amplitude value; and

vi) determining the distance between these two positions to give the half peak width.

9. A method according to claim 6 or 7, wherein an estimate of the relative velocity between the interrogation signal and the information carrier during its interaction with each of the magnetic elements is determined by measuring the separation between the two half peaks of opposite polarity.

10. A method according to any one of claims 1,2 or 3, wherein the frequency of the detected response generated by said magnetic elements is the fundamental frequency of the interrogation signal.

11. A method according to claim 10, wherein a graphical representation of the response signal is obtained by plotting the amplitude of the detected signal against time, wherein the presence of a magnetic element is indicated by a peak in the detected response signal.

12. A method according to claim 11, wherein the peaks in the detected response signal are identified by the following steps:

- i) obtaining a contiguous set of sample points from the detected response signal;
- ii) sorting the samples points into an order of ascending magnitude;
- iii) finding the median value from the sorted

samples and subtracting this value from each of the sample points;

5 iv) testing the sample points in order to identify the peaks, wherein a peak is identified by the presence of lower magnitude signals either side of the signal point being tested.

10 13. A method according to claim 12, wherein an estimate of the relative velocity between the interrogation signal and each of the magnetic elements is determined by:

15 i) determining the two positions either side of the peak at which the amplitude of the detected response signal is a predetermined fraction of the peak amplitude value; and

 ii) determining the distance between these two positions to give the peak width.

20 14. A method according to any one of claims 6 to 13, wherein the velocity of the interrogation signal, with respect to each magnetic element, is determined from the values of each of the peak or half peak widths.

25 15. A method according to any preceding claim, wherein the velocity function of the interrogation signal is modelled by a polynomial function, the coefficients of which are determined by the estimates of the velocity of the interrogation signal at each magnetic element.

30

16. A method according to claim 15, wherein said mathematical function is integrated with respect to time so as to determine the size of the gaps between each of the magnetic elements.

35

17. A method according to any preceding claim,

wherein the size of the measured gaps between each adjacent pair of magnetic elements are modelled by $A + mG$, wherein A is a first fixed value; m is an integer (which may be zero); and G is a second fixed value.

5

18. A method according to any preceding claim, further comprising the step of decoding a variation in length of the magnetic elements, wherein the amplitude of the detected signal response is directly related to the length of the element.

10

19. A method according to claim 18, wherein the length of at least one of the magnetic elements is or are known, thereby acting as a reference element, with respect to which the lengths of the other magnetic elements can be determined.

15

20. A method according to any one of claims 15 to 18, further comprising the step of determining an error metric of the velocity function.

20

21. A method according to any one of claim 17, further comprising the step of determining an error metric of the measured gaps between the magnetic elements compared with the gap widths as modelled by $A+mG$ where m is a decoded integer from each measured gap.

25

22. A method according to any one of claims 15 to 18, further comprising the step of determining an error metric of the amplitude of the magnetic response.

30

23. A method according to any one of claims 20, 21 or 22, wherein the decoded information is rejected if the error metric is found to be higher than a threshold level.

Re.: Item V

The invention concerns a method of decoding an information carrier comprising a plurality of magnetic elements having the same width and wherein the relative positions of the elements represent the encoded information (cf. Figure 1a). Determination of the relative positions of the magnetic elements is based on an estimation of the dynamics of motion between an interrogation signal and the information carrier, such estimation using an estimate of the relative velocity determined element by element. Since all the elements have the same (given) width, no dedicated separate reference elements are needed for determining the velocity, thereby providing for space efficiency.

The method of claim 1 is not suggested by the available prior art. WO-A-96 31 790 concerns a tag of the type shown in Figure 9; although this document states at page 15, lines 28-31 that "it then becomes a simple matter to use the lengths and spacings of individual zones or pieces of magnetic material to represent particular code sequences", it is silent as to how the lengths and spaces are actually measured and there is no suggestion to decode the information using an estimate of the relative velocity between the interrogation signal and each of the magnetic elements. Although EP-A-0 790 572 suggests compensation of the effect of speed-variation of an optical bar code reader on detected relative widths of bar elements by measuring the scanning speed of successive characters each comprising a plurality of different-sized code elements and correcting the width values accordingly, it does not and cannot determine an estimate of the relative velocity between the interrogation signal and each of the elements since the width of each such element is a priori unknown, the element width being used as a means to encode the information carrier.

Dependent claims 2-23 concern preferred embodiments of the invention of claim 1 and thus likewise meet the requirements of novelty and inventive step.

Re.: Item VII

The relevant prior art of WO-A-96 31 790 and EP-A-0 790 572 is not acknowledged in the description, contrary to Rule 5.1(a)(ii) PCT.

The summary of the invention on description page 2 is not in conformity with the new

independent claim.

The description at page 3, lines 12-16 and page 6, lines 28-32 (variable element width) is in conflict with the method of claim 1 (elements having same width).

CLAIMS

1. A method of decoding an information carrier comprising a plurality of magnetic elements supported
5 by, or incorporated in, a substrate, wherein the relative positions and/or physical dimensions of said magnetic elements represents the information encoded by said information carrier, the method comprising the steps of:
- 10 i) applying an interrogation signal to each of the elements of said information carrier;
 ii) detecting the response of said magnetic elements to said interrogation signal;
 iii) processing the response detected in ii) so as
15 to determine an estimate of a mathematical function which defines the relative velocity between the interrogating signal and each of the magnetic elements, from which mathematical function the relative positions and/or the relative physical dimensions can be
20 determined.
- 2 A method according to claim 1, wherein said magnetic elements comprise high permeability, low coercivity material having an easy axis of
25 magnetisation.
3. A method according to claim 1 or 2, wherein said interrogation signal comprises regions of high saturating magnetic field contiguous with regions of
30 zero magnetic field.
4. A method according to claim 3, wherein the magnetic elements respond to the interrogation signal by emitting harmonics of the interrogation frequency.
35
5. A method according to claim 4, wherein the

-21-

amplitude of the harmonic frequency detected is plotted against time to give a graphical representation of the response which is used to determine the required mathematical function defining the relative velocity between the interrogating signal and each of the magnetic elements.

6. A method according to claim 5, wherein the required mathematical function is determined by analysing the shape of said graphical representation.

7. A method according to any preceding claim wherein said mathematical function is modelled by a polynomial function.

8. A method according to any preceding claim, wherein said mathematical function is integrated with respect to time so as to determine the relative positions of the magnetic elements.

9. A method according to any preceding claim, wherein the gaps between each adjacent pair of magnetic elements are defined by $A + mG$, wherein A is a first fixed value; m is an integer (which may be zero); and G is a second fixed value.

10. A method according to any preceding claim, wherein the length of the magnetic elements is varied such that the relative lengths of said magnetic elements serves to encode the information carrier.

11. A method according to claim 10, wherein the length of at least one of the magnetic elements is or are known, thereby acting as a reference element, with respect to which the lengths of the other magnetic elements can be determined.

-22-

12. A method according to any preceding claim, wherein an error metric of the mathematical function, which defines the relative velocity between the interrogating signal and each of the magnetic elements, is determined.

13. A method according to any preceding claim, wherein an error metric of the relative positions of the magnetic elements is determined.

14. A method according to any preceding claim, wherein an error metric of the amplitude of the magnetic element response is determined.

15. A method according to any one of claims 12, 13 or 14, wherein the decoded information is rejected if the error metric is found to be higher than a threshold level.

-23-

AMENDED CLAIMS

[received by the International Bureau on 10 January 2001 (10.01.01);
original claims 1, 4-15 replaced by new claims 1, 4-23; remaining
claims unchanged (5 pages)]

1. A method of decoding an information carrier comprising a plurality of magnetic elements supported by, or incorporated in, a substrate, wherein the relative positions of said magnetic elements represents the information encoded by said information carrier, the method comprising the steps of:
- 5
- i) applying an interrogation signal to each of the elements of said information carrier;
- 10
- ii) detecting the response signal of said magnetic elements to said interrogation signal;
- iii) processing the response detected in ii) so as to determine an estimate of the relative velocity between the interrogation signal and each of the magnetic elements *during the interaction of said interrogation signal with each of said magnetic elements* from which the relative positions of the magnetic elements can be determined.
- 15
- 20
2. A method according to claim 1, wherein said magnetic elements comprise high permeability, low coercivity material having an easy axis of magnetisation.
- 25
3. A method according to claim 1 or 2, wherein said interrogation signal comprises regions of high saturating magnetic field contiguous with regions of zero magnetic field.
- 30
4. A method according to any preceding claim, wherein the frequency of the detected response generated by said magnetic elements is a harmonic of the interrogation signal.
- 35
5. A method according to any preceding claim, wherein

the frequency of the detected response generated by said magnetic elements is the second harmonic of the interrogation signal.

5 6. A method according to any claim 4 or 5, wherein a graphical representation of the response signal is obtained by plotting the amplitude of the detected signal against time, wherein the presence of a magnetic element is indicated by two half peaks of opposite
10 polarity in the detected response signal.

7. A method according to claim 6, wherein the half peaks in the detected response signal are identified by the following steps:

- 15 i) obtaining a contiguous set of sample points from the detected response signal;
- ii) sorting the samples points into an order of ascending magnitude;
- iii) finding the median value from the sorted
20 samples and subtracting this value from each of the sample points;
- iv) testing the sample points in order to identify the peaks, wherein a positive polarity half peak is identified by the presence of lower magnitude signals
25 either side of the signal point being tested, and a negative polarity half peak is identified by the presence of higher magnitude signal either side of the signal point being tested.

30 8. A method according to claim 7, wherein the relative velocity between the interrogation signal and each of the magnetic elements is determined by:

- i) determining the two positions either side of the peak at which the amplitude of the detected
35 response signal is a predetermined fraction of the peak amplitude value; and

vi) determining the distance between these two positions to give the half peak width.

5 9. A method according to claim 6 or 7, wherein an estimate of the relative velocity between the interrogation signal and the information carrier during its interaction with each of the magnetic elements is determined by measuring the separation between the two half peaks of opposite polarity.

10 10. A method according to any one of claims 1,2 or 3, wherein the frequency of the detected response generated by said magnetic elements is the fundamental frequency of the interrogation signal.

15 11. A method according to claim 10, wherein a graphical representation of the response signal is obtained by plotting the amplitude of the detected signal against time, wherein the presence of a magnetic element is indicated by a peak in the detected response signal.

20 12. A method according to claim 11, wherein the peaks in the detected response signal are identified by the following steps:

- 25 i) obtaining a contiguous set of sample points from the detected response signal;
- ii) sorting the samples points into an order of ascending magnitude;
- 30 iii) finding the median value from the sorted samples and subtracting this value from each of the sample points;
- iv) testing the sample points in order to identify the peaks, wherein a peak is identified by the presence
- 35 of lower magnitude signals either side of the signal point being tested.

13. A method according to claim 12, wherein an estimate of the relative velocity between the interrogation signal and each of the magnetic elements is determined by:

5 i) determining the two positions either side of the peak at which the amplitude of the detected response signal is a predetermined fraction of the peak amplitude value; and

10 ii) determining the distance between these two positions to give the peak width.

14. A method according to any one of claims 6 to 13, wherein the velocity of the interrogation signal, with respect to each magnetic element, is determined from the values of each of the peak or half peak widths.

15

15. A method according to any preceding claim, wherein the velocity function of the interrogation signal is modelled by a polynomial function, the coefficients of which are determined by the estimates of the velocity of the interrogation signal at each magnetic element.

20

16. A method according to claim 15, wherein said mathematical function is integrated with respect to time so as to determine the size of the gaps between each of the magnetic elements.

25

17. A method according to any preceding claim, wherein the size of the measured gaps between each adjacent pair of magnetic elements are modelled by $A + mG$, wherein A is a first fixed value; m is an integer (which may be zero); and G is a second fixed value.

30

18. A method according to any preceding claim, further comprising the step of decoding a variation in

35

length of the magnetic elements, wherein the amplitude of the detected signal response is directly related to the length of the element.

5 19. A method according to claim 18, wherein the length of at least one of the magnetic elements is or are known, thereby acting as a reference element, with respect to which the lengths of the other magnetic elements can be determined.

10 20. A method according to any one of claims 15 to 18, further comprising the step of determining an error metric of the velocity function.

15 21. A method according to any one of claim 17, further comprising the step of determining an error metric of the measured gaps between the magnetic elements compared with the gap widths as modelled by $A+mG$ where m is a decoded integer from each measured gap.

20 22. A method according to any one of claims 15 to 18, further comprising the step of determining an error metric of the amplitude of the magnetic response.

25 23. A method according to any one of claims 20, 21 or 22, wherein the decoded information is rejected if the error metric is found to be higher than a threshold level.

INTERNATIONAL SEARCH REPORT

(PCT Article 18 and Rules 43 and 44)

Applicant's or agent's file reference HL73059 001MJA	FOR FURTHER ACTION see Notification of Transmittal of International Search Report (Form PCT/ISA/220) as well as, where applicable, item 5 below.	
International application No. PCT/GB 00/ 03006	International filing date (day/month/year) 04/08/2000	(Earliest) Priority Date (day/month/year) 06/08/1999
Applicant FLYING NULL LIMITED		

This International Search Report has been prepared by this International Searching Authority and is transmitted to the applicant according to Article 18. A copy is being transmitted to the International Bureau.

This International Search Report consists of a total of 4 sheets.

☒ It is also accompanied by a copy of each prior art document cited in this report.

1. Basis of the report

- a. With regard to the **language**, the international search was carried out on the basis of the international application in the language in which it was filed, unless otherwise indicated under this item.

☐ the international search was carried out on the basis of a translation of the international application furnished to this Authority (Rule 23.1(b)).

- b. With regard to any **nucleotide and/or amino acid sequence** disclosed in the international application, the international search was carried out on the basis of the sequence listing :

☐ contained in the international application in written form.

☐ filed together with the international application in computer readable form.

☐ furnished subsequently to this Authority in written form.

☐ furnished subsequently to this Authority in computer readable form.

☐ the statement that the subsequently furnished written sequence listing does not go beyond the disclosure in the international application as filed has been furnished.

☐ the statement that the information recorded in computer readable form is identical to the written sequence listing has been furnished

2. ☐ **Certain claims were found unsearchable** (See Box I).

3. ☐ **Unity of invention is lacking** (see Box II).

4. With regard to the **title**,

☒ the text is approved as submitted by the applicant.

☐ the text has been established by this Authority to read as follows:

5. With regard to the **abstract**,

☐ the text is approved as submitted by the applicant.

☒ the text has been established, according to Rule 38.2(b), by this Authority as it appears in Box III. The applicant may, within one month from the date of mailing of this international search report, submit comments to this Authority.

6. The figure of the **drawings** to be published with the abstract is Figure No.

☐ as suggested by the applicant.

☒ because the applicant failed to suggest a figure.

☐ because this figure better characterizes the invention.

1a

☐ None of the figures.

Box III TEXT OF THE ABSTRACT (Continuation of item 5 of the first sheet)

The abstract is changed as follows:

line 2: after 'carriers' insert '(1)';

line 3: after 'elements' insert '(2)'.

CODED LABEL INFORMATION EXTRACTION METHOD

The present invention relates to methods of interpreting coded information carriers and to methods of processing the response of such carriers to an interrogating magnetic field.

In certain types of human and machine-readable information-bearing label, a set of elements is used to represent the information contained in the label. This representation may be made by varying the characteristics of the elements comprising the label, and also by the position in which the label elements are placed. Reading apparatus senses the characteristics and placement of the elements in order to decode the information contained within the label. The elements in the label are sequentially scanned, to discover the presence of the constituent elements and to measure their characteristics and position and thence to decode the information contained by the label.

This application describes label decoding methods by which information represented on such a label can be decoded. Typical label embodiments are where the label is manufactured from a plurality of magnetically active elements supported on a substrate. Information is coded by controlling the relative positions. Independent control of the physical properties of the elements, such as shape may also be used.

In alternative embodiments, information may be coded by controlling the relative angles of orientation of the easy axis of the magnetic elements and in some cases element shape some other physical property can be independently controlled to further encode the information carrier.

In certain types of label decoding system a label consisting of a set of elements is scanned, that is the

elements are activated in turn by applying a signal to which the scanned element responds, and to which the reading apparatus is sensitive. Either or both of the means of generating the scanning signal, and the means of generating the received signal in the reading apparatus select a single elements in turn so that the signal from a particular element may be resolved from that of the other elements.

According to one aspect of the present invention there is provided a method of decoding an information carrier comprising a plurality of magnetic elements supported by, or incorporated in, a substrate, wherein the relative positions and/or physical dimensions of said magnetic elements represents the information encoded by said information carrier, the method comprising the steps of:

- i) applying an interrogation signal to each of the elements of said information carrier;
- ii) detecting the response of said magnetic elements to said interrogation signal;
- iii) processing the response detected in ii) so as to determine an estimate of a mathematical function which defines the relative velocity between the interrogating signal and each of the magnetic elements, from which the relative positions and/or the relative physical dimensions can be determined.

Conveniently, detection of the magnetic response of said magnetic elements may comprise observation of harmonics which are generated by the magnetic element from an applied AC field as its magnetic state is altered by the interrogating magnetic field. The presence of a magnetic element, and details of the physical dimensions of the magnetic element, can advantageously be identified in a plot of the detected amplitude of the harmonic signal. The presence of a set of signals in the otherwise quiescent detected signal

indicates the issuance of harmonic signal by a magnetic element as its magnetic properties are active. The means of scanning may be automatic by electronically scanning the interrogating signal and the receive
5 sensitivity along the label or by an automatic mechanism causing the label elements to be interrogated in turn. Alternatively the scanning may be manually operated where the label is moved past the reading apparatus by hand, or alternatively the reading
10 apparatus or part thereof may be moved past the label by hand.

Information may be advantageously encoded into the label by varying either the length of the material elements, that is the size of the element normal to the
15 longitudinal axis of the label, or the width of the elements. By maintaining the element width constant, variations in element length predominantly cause a change in amplitude of the received signal which can be detected in order to recognise additional coded
20 information.

For a better understanding of the present invention and to show how the same maybe carried into effect, reference will now be made by way of example to
25 the accompanying drawings in which:

Figure 1a shows a coded information carrier according to the present invention;

Figure 1b shows the variation in amplitude of the second harmonic frequency as the information carrier is
30 subjected to an interrogating magnetic field;

Figure 1c shows the receive signal from a single magnetic element;

Figure 1d shows the received fundamental signal from three magnetic elements;

35 Figure 2a shows the relative variation of the received second harmonic signal with element length;

Figure 2b shows the relative variation of received fundamental signal with element length;

Figure 3a show a coded information carrier according to the present invention, wherein the magnetic element are length coded;

Figure 3b shows the receive signal from an information carrier having length coding;

Figure 4a shows the positions of the half peaks of the detected signal shown in Figure 3b;

Figure 4b shows the magnitude of the double peaks in amplitude units;

Figure 4c shows a plot of the double peak separations versus double peak position;

Figure 4d shows a plot of the velocity estimates of selected points versus time;

Figure 4e shows the resultant fit of gap number to integer grid.

Fig 1a shows a plan view of a label 1 comprising a plurality of magnetic elements 2. The elements are made out of high permeability, low coercivity magnetic thin film material such as Atalante manufactured by IST(Belgium). In this particular example the elements are substantially equal in size and have dimensions of 1mmx1.5mm. The easy axis of the material is arranged so as to be parallel with the longitudinal axis of the label.

In order to interrogate the label 1, a reading antenna is passed by the label subjecting each element in turn to a region of null magnetic field formed by a permanent magnet arrangement. That is a magnetic field comprising regions of high saturating magnetic field contiguous with regions of zero magnetic field. A superimposed high frequency field, in this case 6.348 kHz, causes the material element to switch when it is present in the magnetic null. In other words the

element is driven over its B-H loop as it passes through the zero magnetic field region. A receive coil is used to detect the harmonic signals resulting from the element switching, and the received harmonic signal is mixed to baseband and filtered prior to digitisation.

Figure 1b shows a typical signal received from such a label, wherein the read head is passed in proximity with the information carrier and is arranged to detect the second harmonic of the element switching signals. The signal from a single element is shown in Fig 1c which shows two half peaks 4 and 5 of opposite sign with a zero crossing. It can be seen that the label signal approximates a superposition of single element responses at each position in which there is an element.

The signal is sampled with a fixed sample rate, and converted to a digital representation in an analogue to digital converter. The sample rate must be fast enough to capture the signal information in accordance with the Nyquist criterion, preferably with anti-aliasing filtering prior to the sampling operation.

The sample number of the centre of each element response depends upon the time at which the element passed the read head.

In addition, the width of the element response depends upon the speed at which the element passed the read head. Information about the dynamics of the relative motion of the tag and the read head can therefore be inferred from measuring the width of the signal. This can be achieved by measuring the width of the positive going and negative going peak associated with the element. It can also be achieved by measuring the separation between the positive and negative going peaks. This speed estimate is fundamental to estimates

of the dynamics of motion and allows the information in the label to be decoded reliably without compromising the available code space by adding regular features in the label.

5 In alternative implementations of the reading apparatus, the scanning motion of the magnetic null relative to the label may be achieved by electronically scanning using a set of excitation coils that are driven in a phased manner so as to cause the magnetic
10 null to propagate in space. The null may be scanned at a speed which allows the switching of the label elements to be detected directly from the receive coils without needing to superimpose a separate high frequency excitation field. In this case the material
15 element response coupled into the receiver is a single peak.

 Fig 1d shows 3 adjacent peaks 6, 7 and 8 of the fundamental signal from 3 magnetic elements recorded from a reading system employing electronic scanning. In
20 this case the width of the response from each magnetic element can be used to provide an estimate of the velocity of the scanning null as it passed over the element being scanned. This information can be used to estimate the detailed dynamics of motion and the errors
25 arising from the system and also from misalignment of the label with respect to the nominal read axis of the read head.

 Information can be encoded into the label by varying the length of the material elements, that is
30 the size of the element normal to the longitudinal axis of the label, or the width, that is the size of the element along the longitudinal axis.

 By maintaining the element width constant, variations in element length predominantly cause a
35 change in amplitude of the received signal as illustrated in Fig 2a for the mechanically scanned

second harmonic system, and in Fig 2b for an electronically scanned system detecting the fundamental signal received from the label.

A set of linear test labels with 3 elements was manufactured with the element positions at 0mm, 1.5mm, 3mm along the longitudinal axis of the label. The element widths were 1mm and the length of the centre element varied between 1mm and 2mm. For each label, in Fig 2a, the peak position, the half peak width, the half peak separation and the amplitude difference between the half peaks is advantageously measured. The relative variation of these parameters of the central test element compared with the outer elements, which were maintained at constant length, may be plotted as shown in figure 2b. The measured central element amplitude (vampr), relative to the outer elements, shows a clear, near linear relationship to central element length. The measured central element relative position (vposr), width (vwidr) and separation (vsepr) parameters do not vary significantly with central element length, over and above the effects of experimental errors and imperfections in the manufacture of the test labels.

Similarly Fig 2b shows the relative variation of measured central element amplitude, position and width with element length when the test labels were measured in an electronically scanning reading system and shows a similar near linear relationship to the mechanically scanned reading method receiving second harmonic signals.

A label in which element length has been used to encode additional information is shown in Fig 3a, which shows a label 10 in which two element [with elements of one of two] lengths are used to modulate the elements in the code. The corresponding received signal is shown in Fig 3b in which a difference in

received amplitude from elements of different lengths can be observed. A typical design goal is to maximise the range at which a label may be read. A compromise is needed to maximise reading range for a 2-length label, at the same time as maximising the ability to discriminate the lengths of individual elements. In order to discriminate the length of label elements reliably, certain of these elements may be constrained to be at a known length to act as a reference. In the example illustrated in 3a, the 2 end elements, 12 and 13, of the label are maintained at maximum length to act as a reference. A design rule may also constrain a certain number of the inner elements to also be at maximum length. The reference elements may be at any a priori fixed position, or at a position determined by an a priori rule.

The half peak width, or half peak separation can be measured and, in the case of a reader detecting the second harmonic of the label signal, can be used to form an estimate of the velocity of the interrogation field, at the time when a particular element was scanned. Alternatively, in the case of a reader detecting the fundamental of the label signal, an estimate of the peak width can be used to form an estimate of the velocity of the scanning, at the time when the element was scanned. These estimates are typically K/w_{est} where K is some constant, and w_{est} is the estimate of width or half peak separation, as appropriate. The value of K typically depends on parameters of the reader, the element shape and the position of the element relative to the read antenna. Since K varies with element properties and to facilitate the estimation of the scanning dynamics, K may only be estimated to for elements of the same type based on the amplitude of the element signals.

The first step in processing a received signal

such as shown in Fig 1b or Fig 3b is to estimate the parameters of the peaks contained within the signal. This is achieved with the following steps:

- 5 1 The signal is delimited, that is the continuous received signal is broken up into a contiguous set of samples containing the received signal from one label, or a set of peaks that is likely to contain enough information to decode the label, in the case
10 of non-registered repeating codes.
- 15 2 The signals from this delimited period are sorted into order of ascending magnitude. An indexed sort function, for example using the Quicksort method, such as index() (Numerical Recipes in C, second
20 edition, ISBN 0 521 43108 5) is appropriate so that the original location of the point of any rank can be quickly found. The median value is found from the sorted data and provides a good estimate of the quiescent signal level. The median is subtracted from
25 all signal points so that the quiescent level is close to zero.
- 30 3 The positive half peaks are found by working down from the largest signal in magnitude in the sorted data, testing the signal points as follows. If the
35 test signal point is a peak, that is its adjacent signals are lower in magnitude it is estimated as a positive half peak, and its amplitude is interpolated by interpolation of the peak and its neighbouring points.
- 40 4 From each positive half peak found, the signal is scanned forward and backwards to find the points at which it falls below a defined magnitude relative to the peak, this is interpolated to a fraction of a sample period A typical magnitude value is 0.8 of the
45 peak value found. The half peak width is estimated as

-10-

the difference in position between these points. The half peak position is estimated as the average of these two points. The half peak is rejected if it overlaps with any other pre-existing peak in the list, that is its width about its position interferes the width about any other peak position in the list. If it is not rejected, the half peak is appended to a list of half peaks.

5

10

5 The peak finding process stops when the magnitude of the next highest point falls below an absolute threshold, or when it falls below a defined fraction of the largest magnitude signal, for example 0.3 of the largest magnitude signal, or if a limit for the number of peaks is reached.

15

20

6 The negative half peaks are found by working up in magnitude from the lowest signal in magnitude in the sorted data, testing signal points of increasing magnitude. If the test signal point is a negative peak, that is its adjacent signals are higher in magnitude it is estimated as a negative half peak, and its amplitude is interpolated by interpolation of the peak and its neighbouring points.

25

30

35

7 For each negative half peak, the signal is scanned forward and backwards to find the points at which it increases above a defined magnitude relative to the negative peak, this is interpolated to a fraction of a sample period. The half peak width is estimated as the difference in position between these points. The half peak position is estimated as the average of these two points. The half peak is rejected if it overlaps with any other pre-existing peak in the list, that is its width about its position interferes the width about any other peak position in the list. If it is not rejected by this test it is then appended to a list of half peaks.

-11-

8 The negative peak finding process stops when the
magnitude of the next highest point falls above an
absolute threshold, or when it falls above a defined
fraction of the largest magnitude signal, or if a
5 limit for the number of peaks is reached.

9 The resultant list of positive and negative half
peaks is then sorted into range order. This process
will interleave the consecutive half peaks.

10 Merging range consecutive pairs of half peaks in
the range sorted half peak list forms a list of
double peaks. The amplitude of the merged double peak
is the difference in amplitude of two half peaks
being merged. The position of the merged double peak
is the average of the two half peak positions. The
15 width of the merged double peak is the average of two
half-peak widths. The separation of the merged double
peak is the difference between the two half peak
positions.

20 The results of this half peak finding process are
illustrated in Fig 4a which shows the half peaks found
when the signal shown in Fig 3b is processed, and shows
the output of step 9 above. These peaks are shown with
a cross at the located position and estimated
25 amplitude. Fig 4b shows the magnitude of the double
peaks in amplitude units. In this case the amplitudes
are negative since the first half peak is a negative
going peak. The difference in peak amplitude between
the full length and reduced length elements in the
30 label can be clearly seen. Fig 4c shows the double peak
separations versus double peak position showing the
variation across the scanning of the label.

In the case of a fundamental signal where there is
just one peak per element, such as that shown in Fig
35 1d, a simpler process is may be used, missing steps 6

to 10 above since there is no need to find and merge double peaks.

There are N label elements positions whose centres are located at $X_1 \dots X_N$ along the longitudinal axis of the label, and whose position we wish to estimate. It is assumed that X_1 is at position 0.0 and that the final element, X_N is at the known position of corresponding to the length of the label L .

The peak list as described above contains estimates of the sample number, and hence times T_i at which the reader detected a double peak. For each element i , the time T_i is simply the position in samples where the peak was measured multiplied by the sample period, which is the reciprocal of the sampling rate.

By using the estimated double peak width or double peak separation for each of the N peaks denoted W_i a velocity estimate for the i^{th} peak is $VE_i = 1/W_i$ at time T_i .

The order M velocity function of time is modelled by a polynomial function. M is chosen to allow sufficient degrees of freedom to model the dynamics of label motion sufficiently accurately. It can range from 1 (constant acceleration model) upwards.

$$VF(t, M) = a_0 + a_1 t + a_2 t^2 + a_3 t^3 + \dots + a_M t^M$$

where $\{a\}$ are a set of polynomial coefficients to be determined.

The squared error for velocity estimate VE_i at time T_i is $E_i^2 = (VE_i - VF(T_i, M))^2$

The total sum of the squared errors is $ES(M) = E_1^2 + E_2^2 + \dots + E_N^2$ which is minimised by varying the $M+1$ parameters a_0, a_1, \dots, a_M . This is achieved by the method of

least squares to find the optimum parameters in the least squares sense.

Define the matrix X to contain the T_i values raised to a given power. For example column 0 row i of X contains T_i^0 and column M row 4 of X contains T_4^M . Define the vector V to contain the velocity estimates VE_i . For example the element in row 4 of V contains VE_4 .

Some linear combination of the columns in X will be closest to the vector V in the least-squares sense. The coefficients of this linear combination will be the coefficients of the best-fitting polynomial. If A is the vector of length $M+1$ that holds the coefficients, the problem is to find the value for A that gives the best "near-solution" to the system of equations $XA = V$. If the columns of X are independent, the best choice for A is given by:

$$A = (X^T X)^{-1} (X^T V)$$

Where " T " represents matrix transpose and " $^{-1}$ " represents matrix inversion. The coefficient a_i is then the element from row i of A . This may be efficiently calculated by using methods such as LU decomposition, for examples the functions `ludcmp()` and `lubksb()` (Numerical Recipes in C, second edition, ISBN 0 521 43108 5)

This process is illustrated in Fig 4d where the velocity estimates W_i that were computed from the double peak separation data of Fig 4c are shown, those points marked "full data" contain the velocity estimates from all the peaks. In this example case, only the estimates from peaks with high amplitude, see Fig 4b, are selected for velocity fitting. These selected points are marked "Data points used in fit". If the label known a priori to have elements of the same size then all elements would have been used. A least squares fit

of order 2 was used and the continuous line shows the estimated velocity function as a function of sample number. A least squares fit of order 1, 2 or 3 is typically sufficient to model the velocity function with sufficient accuracy.

Error metrics are computed to allow the decoding algorithms to assess the quality of the read. A useful normalised velocity error metric, denoted e_{vel} , to quantify how well the velocity function fitted the data observed is defined. It is the sum of squares of the normalised error defined as :

$$e_{vel} = \sum (E_i^2 / VE_i^2) \text{ for } i=1..N$$

The vector A could also be estimated by an iterative minimisation procedure such as Powell's method.

The above procedure can be repeated for varying model order M on the same data in order to find the best approximation. Preferably this is the solution with the smallest number of degrees of freedom, that fits the data read by the reader with the lowest error metrics.

Analytical interrogation and normalisation of tag length

The velocity fit function is

$VF(t, M) = a_0 + a_1 t + a_2 t^2 + a_3 t^3 + \dots + a_M t^M$ This may be analytically integrated to find the positional fit function

$$P(t, M) = Q + a_0 t + (1/2) a_1 t^2 + (1/3) a_2 t^3 + \dots + (1/(M+1)) a_M t^{M+1}$$

where Q is an arbitrary constant of integration, set to zero.

We know that the position of label element 1 is at 0.0.

-15-

We also know that the position of element N, the last element scanned is L, the length of the label. The final estimates of element position are:

$$5 \quad XE_i = L \cdot (P(X_i, M) - P(X_1, M)) / (P(X_N, M) - P(X_1, M))$$

Binning of data

10 There are N positional estimates XE_1 to XE_N from which N-1 gaps may be estimated.

Typically the gaps have the minimum gap subtracted, and are divided by the minimum gap, to give a real number representing the number of gap increments. The nearest integer is then taken to represent the gap for subsequent decoding. This can be expressed as:

20 The N-1 normalised gaps R_j are calculated by

$$R_j = (XE_{j+1} - XE_j - \text{Minimum_Gap}) / \text{Gap_Increment} \quad \text{for } j=1 \dots N-1$$

The normalised gaps are then converted to their nearest integer representation

25 $G_j = \text{int}(R_j + 0.5)$ for $j=1 \dots N-1$, where $\text{int}(x)$ means the truncated integer portion of x .

30 In this way, the gaps between each adjacent pair of magnetic elements can be defined by $A + mG$, wherein A is a first fixed value; m is an integer (which may be zero); and G is a second fixed value

35 One useful error metric, denoted e_{\max} , is defined as the maximum magnitude of the difference between G_j and R_j . Another useful error metric, denoted e_{av} , is the average magnitude of the difference between G_j and R_j .

Fig 4e shows the gap sequence data R_i computed from the data in Fig 4a-d, and shows the close correspondence or "snapping" to an integer grid, giving a high confidence that the gaps have been correctly measured. The gap sequence in this case is 3,2,2,1,7,0,0,2,1 .

Enumeration algorithms

Depending on the coding scheme used, the gap sequence is enumerated to a unique decoded value. Various codes exist that have different properties for example those codes allowing read direction to be determined, or those that allow non-registered operation, that is allowing the gap sequence to start at any position, for example a portion of a repeating gap sequence. The code may be determined a priori, or diagnosed by examining the read signals for the number of material elements present, or by estimating the sum of the gap numbers. It is preferable to determine this beforehand in order to minimise the chance of misinterpreting a given set of read data.

For certain codes, the number of elements in the label may be one of a range of possible values, with fixed label length in order to increase the number of possible codes.

The direction finding codes are preferably used where amplitude coding is used to allow the amplitude information to be associated with the correct element.

Amplitude threshold estimation of elements

Where it is desired to detect the size of the received element signal, for example when the elements may be of two or more sizes, reference elements may be placed in

the set of elements used to make the label. In one embodiment, the end elements are constrained to be the largest element size to act as a reference. Other embodiments may place reference elements that have some unique characteristic, or may be identified by an a priori rule.

The amplitudes are measured and used to compute normalised amplitudes. This is because the reference elements may be significantly different in magnitude. This may be due to the scanning process varying the distance or angle of the read head from the label during the read, or other factors.

The estimates of element position XE_i may be used for linear interpolation of the reference amplitude along the label. The reference amplitude predicted at the estimated position of the element divides the measured element amplitudes to normalise the amplitudes. The normalised amplitudes should be nominally 1.0 for an element the same size as the reference element.

Threshold levels are set to provide discrimination between the possible element amplitudes and to classify the amplitude of the element into one of an alphabet of values. For example if there are two values then the amplitude is either high or low. For example a half length element may have an amplitude, on average, half the reference amplitude ie 0.5. In this case, the threshold level should be set to approximately 0.75 in order to determine if the element was full length or half length.

Preferably a code is used which enables the direction of reading of the label to be determined by the sequence of gaps that resulted. In this case the

elements can be uniquely identified and it is known which element of the label to associate with the decoded amplitude information.

5 In the case of the label data shown in Fig 4b, denoting the amplitudes of the signals from the elements as "H" for high amplitude and "L" for low amplitude, the elements are categorised as H,L,H,L,H,L,H,L,L,H. A larger alphabet of elements could be used by using a
10 label with more possible shapes, for example. The categorisations are then converted to decoded data.

A typical scheme allows the inner elements only to contain data, ignoring the end elements, which are
15 references, and maps H to a logical 0 and L to a logical 1 so that the binary data word from the example data would be 10101011. In this scheme up to 256 amplitude codes can be represented from 8 inner elements. Preferably the codes used are constrained to
20 ensure that a certain number of elements in the label, for example 4 are at full length to facilitate velocity estimation. If this constraint is used, the number of amplitude codes is reduced by 37 to 219 in this case.

25 An amplitude error metric eamp is defined which is the normalised amplitude difference between the largest half length element diagnosed to the smallest full length element diagnosed. If there is no half-length element diagnosed, eamp is defined as the smallest full
30 length element amplitude. In a label containing different sized elements, a large value for this metric suggests a clear discrimination in amplitude between elements of different types. Smaller values indicate increasing risk that an element may be categorised as
35 the wrong amplitude.

Error Metrics

The error metrics defined: evel, emax, eav and eamp can be used to determine the read quality. evel, emax and eav are preferably small and eamp high. Independent thresholds for these quantities are independently established. These thresholds are based on measured values for many labels in many read operations over the range of reading ranges and scanning dynamics expected in an application. This is done to minimise the probability of a wrong code at the same time as maintaining a high probability of a correct read.

During the read decoding process, if the computed error metrics are higher than the threshold value in the case of evel, emax and eav then the read is rejected. If the error metric is lower than the threshold in the case of eamp then the read is rejected.

CLAIMS

1. A method of decoding an information carrier comprising a plurality of magnetic elements supported
5 by, or incorporated in, a substrate, wherein the relative positions and/or physical dimensions of said magnetic elements represents the information encoded by said information carrier, the method comprising the steps of:

10 i) applying an interrogation signal to each of the elements of said information carrier;

ii) detecting the response of said magnetic elements to said interrogation signal;

15 iii) processing the response detected in ii) so as to determine an estimate of a mathematical function which defines the relative velocity between the interrogating signal and each of the magnetic elements, from which mathematical function the relative positions and/or the relative physical dimensions can be
20 determined.

2 A method according to claim 1, wherein said magnetic elements comprise high permeability, low coercivity material having an easy axis of
25 magnetisation.

3. A method according to claim 1 or 2, wherein said interrogation signal comprises regions of high saturating magnetic field contiguous with regions of
30 zero magnetic field.

4. A method according to claim 3, wherein the magnetic elements respond to the interrogation signal by emitting harmonics of the interrogation frequency.
35

5. A method according to claim 4, wherein the

amplitude of the harmonic frequency detected is plotted against time to give a graphical representation of the response which is used to determine the required mathematical function defining the relative velocity between the interrogating signal and each of the magnetic elements.

6. A method according to claim 5, wherein the required mathematical function is determined by analysing the shape of said graphical representation.

7. A method according to any preceding claim wherein said mathematical function is modelled by a polynomial function.

8. A method according to any preceding claim, wherein said mathematical function is integrated with respect to time so as to determine the relative positions of the magnetic elements.

9. A method according to any preceding claim, wherein the gaps between each adjacent pair of magnetic elements are defined by $A + mG$, wherein A is a first fixed value; m is an integer (which may be zero); and G is a second fixed value.

10. A method according to any preceding claim, wherein the length of the magnetic elements is varied such that the relative lengths of said magnetic elements serves to encode the information carrier.

11. A method according to claim 10, wherein the length of at least one of the magnetic elements is or are known, thereby acting as a reference element, with respect to which the lengths of the other magnetic elements can be determined.

12. A method according to any preceding claim, wherein
an error metric of the mathematical function, which
defines the relative velocity between the interrogating
signal and each of the magnetic elements, is
5 determined.

13. A method according to any preceding claim, wherein
an error metric of the relative positions of the
magnetic elements is determined.
10

14. A method according to any preceding claim,
wherein an error metric of the amplitude of the
magnetic element response is determined.

15. A method according to any one of claims 12, 13 or
14, wherein the decoded information is rejected if the
error metric is found to be higher than a threshold
level.
15

AMENDED CLAIMS

[received by the International Bureau on 10 January 2001 (10.01.01);
original claims 1, 4-15 replaced by new claims 1, 4-23; remaining
claims unchanged (5 pages)]

1. A method of decoding an information carrier
comprising a plurality of magnetic elements supported
by, or incorporated in, a substrate, wherein the
relative positions of said magnetic elements represents
the information encoded by said information carrier,
the method comprising the steps of:

i) applying an interrogation signal to each of the
elements of said information carrier;

ii) detecting the response signal of said magnetic
elements to said interrogation signal;

iii) processing the response detected in ii) so as
to determine an estimate of the relative velocity
between the interrogation signal and each of the
magnetic elements. ~~during the interaction of said
interrogation signal with each of said magnetic
elements~~ from which the relative positions of the
magnetic elements can be determined, ~~wherein~~

2. A method according to claim 1, wherein said
magnetic elements comprise high permeability, low
coercivity material having an easy axis of
magnetisation.

3. A method according to claim 1 or 2, wherein said
interrogation signal comprises regions of high
saturating magnetic field contiguous with regions of
zero magnetic field.

4. A method according to any preceding claim, wherein
the frequency of the detected response generated by
said magnetic elements is a harmonic of the
interrogation signal.

5. A method according to any preceding claim, wherein

the frequency of the detected response generated by said magnetic elements is the second harmonic of the interrogation signal.

5 6. A method according to any claim 4 or 5, wherein a graphical representation of the response signal is obtained by plotting the amplitude of the detected signal against time, wherein the presence of a magnetic
10 element is indicated by two half peaks of opposite polarity in the detected response signal.

7. A method according to claim 6, wherein the half peaks in the detected response signal are identified by the following steps:

- 15 i) obtaining a contiguous set of sample points from the detected response signal;
- ii) sorting the samples points into an order of ascending magnitude;
- iii) finding the median value from the sorted
20 samples and subtracting this value from each of the sample points;
- iv) testing the sample points in order to identify the peaks, wherein a positive polarity half peak is identified by the presence of lower magnitude signals
25 either side of the signal point being tested, and a negative polarity half peak is identified by the presence of higher magnitude signal either side of the signal point being tested.

30 8. A method according to claim 7, wherein the relative velocity between the interrogation signal and each of the magnetic elements is determined by:

- i) determining the two positions either side of the peak at which the amplitude of the detected
35 response signal is a predetermined fraction of the peak amplitude value; and

vi) determining the distance between these two positions to give the half peak width.

5 9. A method according to claim 6 or 7, wherein an estimate of the relative velocity between the interrogation signal and the information carrier during its interaction with each of the magnetic elements is determined by measuring the separation between the two half peaks of opposite polarity.

10 10. A method according to any one of claims 1,2 or 3, wherein the frequency of the detected response generated by said magnetic elements is the fundamental frequency of the interrogation signal.

15 11. A method according to claim 10, wherein a graphical representation of the response signal is obtained by plotting the amplitude of the detected signal against time, wherein the presence of a magnetic element is indicated by a peak in the detected response signal.

20 12. A method according to claim 11, wherein the peaks in the detected response signal are identified by the following steps:

25 i) obtaining a contiguous set of sample points from the detected response signal;

ii) sorting the samples points into an order of ascending magnitude;

30 iii) finding the median value from the sorted samples and subtracting this value from each of the sample points;

35 iv) testing the sample points in order to identify the peaks, wherein a peak is identified by the presence of lower magnitude signals either side of the signal point being tested.

13. A method according to claim 12, wherein an estimate of the relative velocity between the interrogation signal and each of the magnetic elements is determined by:

5 i) determining the two positions either side of the peak at which the amplitude of the detected response signal is a predetermined fraction of the peak amplitude value; and

10 ii) determining the distance between these two positions to give the peak width.

14. A method according to any one of claims 6 to 13, wherein the velocity of the interrogation signal, with respect to each magnetic element, is determined from
15 the values of each of the peak or half peak widths.

15. A method according to any preceding claim, wherein the velocity function of the interrogation signal is modelled by a polynomial function, the
20 coefficients of which are determined by the estimates of the velocity of the interrogation signal at each magnetic element.

16. A method according to claim 15, wherein said
25 mathematical function is integrated with respect to time so as to determine the size of the gaps between each of the magnetic elements.

17. A method according to any preceding claim,
30 wherein the size of the measured gaps between each adjacent pair of magnetic elements are modelled by $A + mG$, wherein A is a first fixed value; m is an integer (which may be zero); and G is a second fixed value.

35 18. A method according to any preceding claim, further comprising the step of decoding a variation in

length of the magnetic elements, wherein the amplitude of the detected signal response is directly related to the length of the element.

5 19. A method according to claim 18, wherein the length of at least one of the magnetic elements is or are known, thereby acting as a reference element, with respect to which the lengths of the other magnetic elements can be determined.

10 20. A method according to any one of claims 15 to 18, further comprising the step of determining an error metric of the velocity function.

15 21. A method according to any one of claim 17, further comprising the step of determining an error metric of the measured gaps between the magnetic elements compared with the gap widths as modelled by $A+mG$ where m is a decoded integer from each measured gap.

20 22. A method according to any one of claims 15 to 18, further comprising the step of determining an error metric of the amplitude of the magnetic response.

25 23. A method according to any one of claims 20, 21 or 22, wherein the decoded information is rejected if the error metric is found to be higher than a threshold level.
